Title:	Lattices in Euclidean space
Authors:	<a href="#">Agrawal, Shreepad</a>
Keywords:	Lattices Euclidean
Issue Date:	May-2024
Publisher:	IISER Mohali
Abstract:	<p>A lattice <math>L</math> is a finitely generated <math>\mathbb{Z}</math>-submodule of a vector space such that it contains a basis of the vector space over <math>\mathbb{Q}</math>. Given a bilinear form on <math>L</math>, we define a quadratic form <math>Q(x)</math> on the lattice. A lattice <math>L</math> is said to be positive lattice if <math>Q(x) &gt; 0</math> for all <math>x \in L \setminus \{0\}</math>. If <math>L</math> and <math>M</math> are positive lattices, we can define the tensor product <math>L \otimes M</math> which is also a positive lattice. We define the <math>\min(L)</math> for a positive lattice to be the <math>\min\{Q(x) \mid x \in L \setminus \{0\}\}</math>. Then <math>\min(L \otimes M) \leq \min(L)\min(M)</math>. The natural question is when does the equality hold. The equality holds for every <math>M</math>, if <math>L</math> is of E-type. We'll explore these special lattice and their properties. The second part of my thesis is regarding scalar extension of lattices. Let <math>L</math> and <math>M</math> be two positive lattices, <math>F</math> be a finite extensions of <math>\mathbb{Q}</math> and <math>R_F</math>, the ring of integers of <math>F</math>. Then <math>R_F \otimes L</math> is called the scalar extension of <math>L</math>. Assume there exists an isometry <math>\sigma</math> such that <math>\sigma(L) = M</math>. Then <math>\sigma</math> is also an isometry between the scalar extensions of lattices, i.e. <math>\sigma(R_F \otimes L) = R_F \otimes M</math>. The interesting questions is, assume there exists an isometry between the scalar extension of lattices. When does the isometry passes down to lattices?</p>
